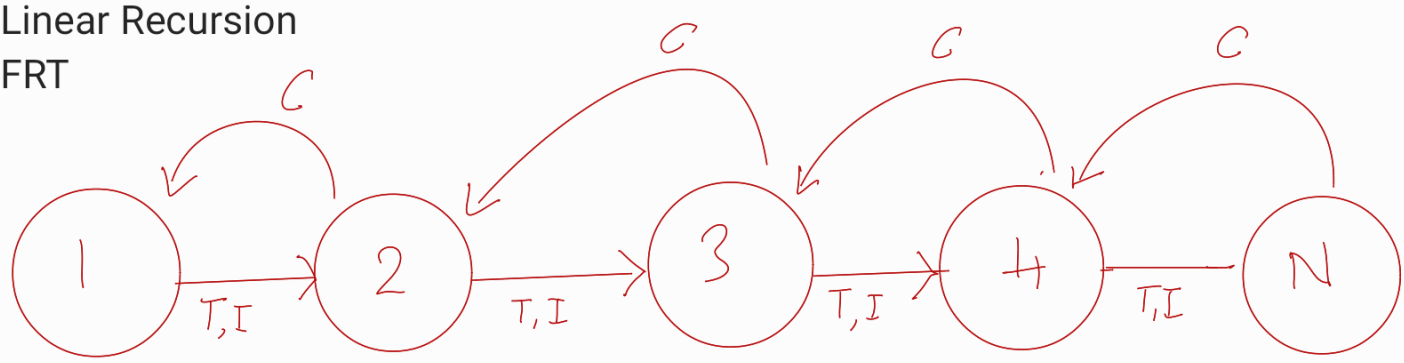
Linear Recursion VS Binary Recursion

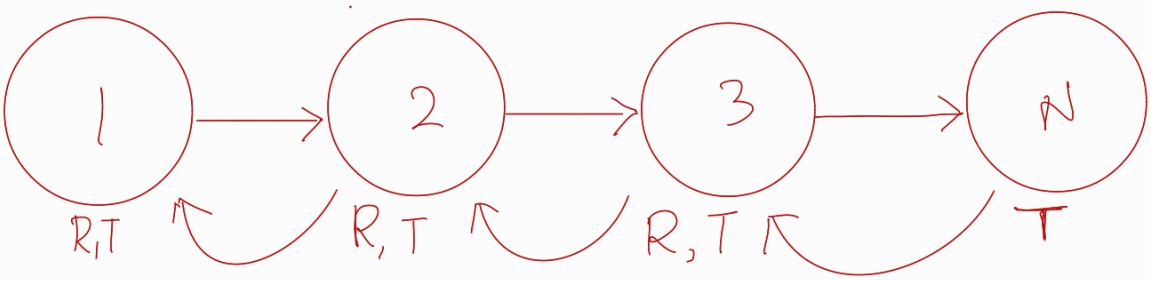
Linear Recursion

FRT



- Tail Recursion
- Memoisation at Time when value is passed to next Recursive Call.
- Constant Value Return.
- Traverse at time of GO.

BRT



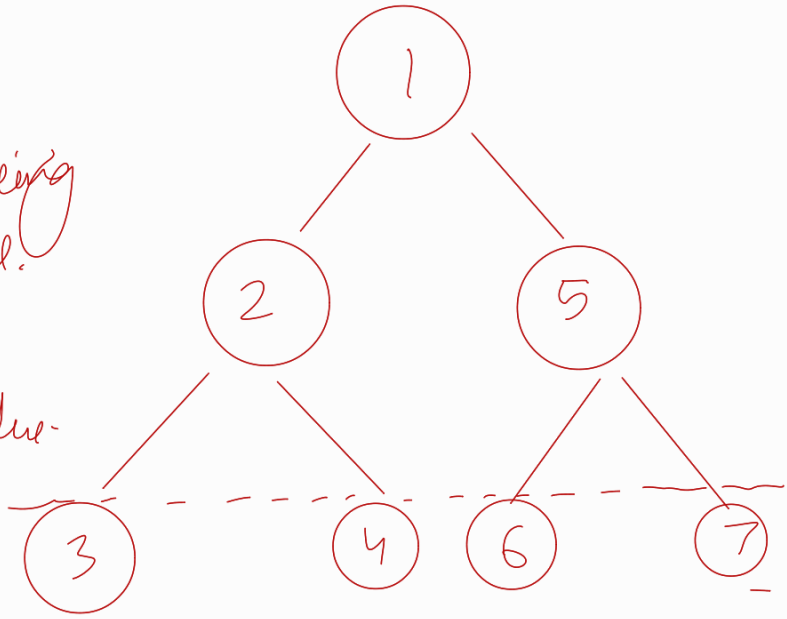
- Head Recursion
- Memoisation at the time of Return
- The Base Conditioned Node just Traverse the value and returned to where it was called.

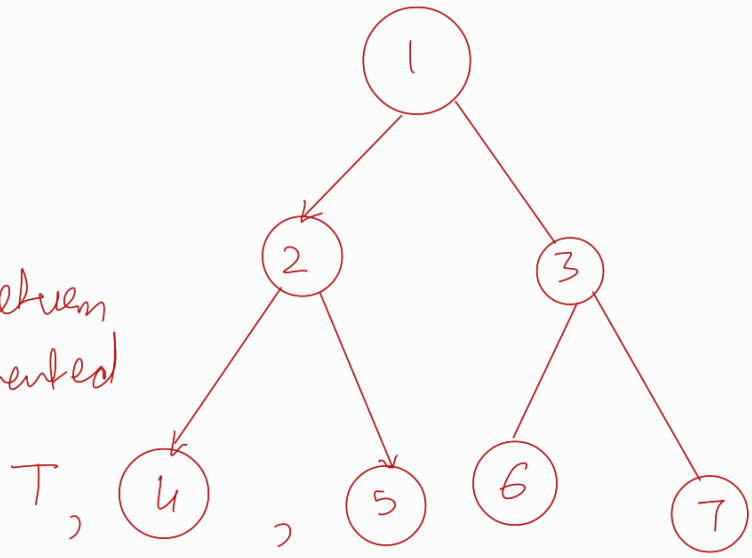
- The other nodes have both Traversed Value and Returned Value to manipulate at the time of COME.

Binary Recursion

FRT

- Tail Recursion
- Memoisation at the time of value being passed to the next recursive call.
- Constant Value return to the previous Node from both side called left Returned Value and right Returned Value.
- Left Increment Returned Values.



BRT


- Head Recursion
- Memoisation at the time of Return
- We return a node a Traversed Value, Left Non-Incremented Return Value and Right Non-Incremented Return Value.
